OPTIMALITY OF VWAP EXECUTION STRATEGIES UNDER GENERAL SHAPED MARKET IMPACT FUNCTIONS

TAKASHI KATO

Abstract. In this short note, we study an optimization problem of expected implementation shortfall (IS) cost under general shaped market impact functions. In particular, we find that an optimal strategy is a VWAP (volume weighted average price) execution strategy when the market model is a Black-Scholes type with stochastic clock and market trading volume is large.

Let $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\geq 0}, \mathtt{P})$ be a stochastic basis. We consider

$$J(x) = \sup_{(\zeta_t)_{0\leq t\leq T}} \mathtt{E}\Big[\int_0^T \zeta_t S_t dt\Big] \tag{1}$$

subject to

$$dS_t = S_t(\mu dV_t + \sigma d\tilde{B}_{V_t} - g(\zeta_t/v_t)dV_t),$$

where $x \geq 0$, $\mu < 0$, $\sigma \geq 0$, $g : [0,\infty) \to [0,\infty)$, $V_t = \int_0^t v_r dr$, $(v_t)_t$ is an $(\mathcal{F}_t)_t$-adapted continuous positive process with $\mathtt{E}[V_T] < \infty$, $(\tilde{B}_{\tilde{t}})_{\tilde{t}\geq 0}$ is an $(\tilde{\mathcal{F}}_{\tilde{t}})_{\tilde{t}\geq 0}$-Brownian motion, and $\tilde{\mathcal{F}}_{\tilde{t}} = \mathcal{F}_{V^{-1}_{\tilde{t}}}$, $(\zeta_t)_t$ is an $(\mathcal{F}_t)_t$-progressively measurable non-negative process satisfying $\int_0^T \zeta_t dt \leq x$ *a.s.*.

Here, S_t (resp., ζ_t) denotes a security price (resp., a trader's selling speed of the security) at time t. g is regarded as a market impact function.

Note that (1) is equivalent with minimizing expected IS cost problem $(xS_0 - J(x))$.

When $v_t \equiv 1$ and g is quadratic, (1) is studied in Section 5.2 of [Kato14], and we see that an optimal strategy is a TWAP (time weighted average price) execution, that is, selling by constant speed, when x is not so large.

This note presents a generalization of the above result. We assume the following conditions for g.

(A1) $g \in C^1((0,\infty)) \cap C([0,\infty))$,
(A2) $g(0) = 0$,
(A3) $h := g' \geq 0$. Moreover, there is a $\zeta_0 \geq 0$ such that h is non-increasing on $(0, \zeta_0]$, and strictly increasing on $[\zeta_0, \infty)$,
(A4) $\lim_{\zeta\to\infty} h(\zeta) = \infty$.

Date: June 1, 2016.

Note that when $\zeta_0 = 0$, g is strictly convex on $[0, \infty)$.

Then, we have:

Theorem 1. *Let $\nu \geq \zeta_0$ be a unique solution to $\nu h(\nu) - g(\nu) = -\mu$. If $x \leq \nu V_T$ a.s., it holds that $J(x) = \frac{S_0}{h(\nu)}(1 - e^{-h(\nu)x})$. The corresponding optimal execution strategy is given as $\hat{\zeta}_t = \nu v_t 1_{\{v_t \leq x/\nu\}}$.*

Next we treat more realistic situation where the trader's execution itself increases the market trading volume, that is,

$$\hat{J}(x) = \sup_{(\zeta_t)_{0 \leq t \leq T}} \mathrm{E}\Big[\int_0^T \zeta_t \hat{S}_t dt\Big] \tag{2}$$

subject to

$$d\hat{S}_t = \hat{S}_t\big(\mu d\hat{V}_t + \sigma d\tilde{B}_{\hat{V}_t} - \hat{g}(\zeta_t/\hat{v}_t)d\hat{V}_t\big), \quad \hat{v}_t = v_t + \zeta_t,$$
$$\hat{V}_t = \int_0^t \hat{v}_r dr, \quad \int_0^t \zeta_t dt \leq x \ a.s..$$

Here, $\hat{g} : [0, 1) \to [0, \infty)$ satisfies (A1) - (A3) replacing ∞ with 1 and the condition $\hat{h}(1-) = \infty$, where $\hat{h} = \hat{g}'$.

Theorem 2. *Let $\hat{\nu} \in [\zeta_0, 1)$ be a unique solution to $\hat{\nu}\hat{h}(\hat{\nu}) - \hat{g}(\hat{\nu}) = -\mu$, and set $\nu = \hat{\nu}/(1 - \hat{\nu})$. If $x \leq \nu V_T$ a.s., it holds that $\hat{J}(x) = \frac{\hat{S}_0}{\hat{h}(\hat{\nu})}(1 - e^{-\hat{h}(\hat{\nu})x})$. The corresponding optimal execution strategy is given as $\hat{\zeta}_t = \nu v_t 1_{\{v_t \leq x/\nu\}}$.*

Proofs of Theorem 1 and 2 are not difficult. We can show them by standard verification arguments. In any case, the optimality of VWAP execution strategies is guaranteed under general g (, $\hat{g}$) whenever x is not so large (in other words, $\operatorname{ess\,inf} V_T$ is not so small).
